- TI - YEAST HAVING LIPASE ON CELL SURFACE AND ITS UTILIZATION
- AB - PROBLEM TO BE SOLVED: To obtain a new DNA which has a secretion signal sequence, a lipase structure gene sequence, a sequence coding for a part of a cell surface localized protein, and a GPI anchor adhesion signal sequence, in this order, and can express lipase on the cell surface.
- SOLUTION: This DNA has a secretion signal sequence, a lipase structure gene sequence, a sequence coding for a part of a cell surface localized protein, and a GPI anchor adhesion signal sequence, in this order, can express lipase on the cell surface, and is useful, for example, for creating a yeast having lipase on its surface, which the yeast is suitable for hydrolyzing lipid, especially for producing 'bio-diesel oil' from waste oil by introducing into a yeast. This DNA is obtained by linking a secretion signal sequence, a lipase structural gene sequence from *Fusarium heterosporum*, a sequence coding for a part of a cell surface localized protein consisting of a yeast α -glutinin sequence, and an anchor adhesion signal sequence, in this order.
